

## Abstract

### TRACING LAYER-2 ROUTE IN NETWORKS BASED ON BROADCAST MEDIUM

5 Tracing the layer-2 devices present between any two systems in a network implemented using  
broadcast medium. A device (receiving device) receives a command including a source and destination  
system identifiers. If the receiving device is not connected directly to the source system, the receiving  
device determines a connecting device connecting directly to the source system. The receiving system  
sends a request packet to the connecting device and receives a response packet. The response packet  
either indicates that the sending device is directly connected to the destination system or indicates a next  
device in the connecting path. The request and response sequence is continued until a sending device  
indicates that the destination system is connected directly.
